

Security risk assessment report

Part 1: Select up to three hardening tools and methods to implement

1. Password policies
2. Multifactor authentication (MFA)
3. Encryption using the latest standards

Part 2: Explain your recommendations

1. Having employees share passwords increases the risk of an incident by a former employee or due to the password leaking. Having password policies will create a layer that prevents attacks such as a brute force attack. The policy is implemented once and updated as needed.
2. MFA will create another layer of security by ensuring anyone who logs in has to verify using two more ways. This is set up once and maintained.
3. This will protect the customer and any other private data using encryption that can be updated. This will create another layer of protection by concealing protected information. This can be updated regularly.
